PATCH CODES FOR COLOR CALIBRATION JOB IDENTIFICATION ENCODING

BACKGROUND OF THE INVENTION

This application is directed to patch codes for color calibration job
5 identification encoding. Typically, there are two phases involved in the color
correction of a color printer: calibration and characterization. Calibration involves
maintaining the printer at a defined state, while characterization involves
determination of the multidimensional transformation or profile that relates device
10 color signals (e.g. CMYK) to spectrophotometric or colorimetric signals (e.g.
CIELAB). Typically, characterization is performed relatively infrequently,
sometimes only once at the factory that produces the printer. Calibration, on the
other hand, needs to be performed frequently to compensate for printer drift and
bring the device back to its nominal state. While the term calibration will be used
15 throughout this application, the ideas also apply equally to the characterization
process.

The calibration process involves sending an image with pre-specified
device signals (i.e. a target) to the printer, and making spectrophotometric
measurements of the print with the use of a spectrophotometric scanner. The
device and spectrophotometric signals together are used to build or update the
20 calibration tables.

In a production environment, many printers, perhaps 30 to 40, might be
going through a calibration process at the same time. In a typical environment,
operators must manually keep track of each printed page, and there can be many
printed target types printed for each printer. The operator must then feed each
25 page to a spectrophotometric scanner and tabulate results of scanning each target
type. The results of each scan must be manually associated to the corresponding
printed target, and to the correct printer. Considering the quantity of pages printed
and the amount of work necessary to manually track each printed page, there is
considerable possibility for error. Pages can be accidentally misordered, and
30 scanning results can accidentally be associated with an incorrect printed target or
printer. This can result in highly inaccurate calibrations, and calls upon the
difficult task of diagnosing the errors.

It would be desirable, therefore, to provide automation to the color printer
calibration process, breaking the cycle where an operator must keep track of all
35 details. It is further desirable that the job identification data be encoded according

to a scheme wherein job identification data is printed according to a protocol and in a format approximately identical to a format of said target.

SUMMARY OF THE INVENTION

5 The present invention automates the color printer calibration process, wherein the spectrophotometric scanner reads job identification data from each printed page where it has been recorded by the calibration system on the printer being calibrated. This job identification data will desirably include encoded printer identification, what part of the calibration is being tested (target), the current date, an operator name, and any additional information deemed necessary
10 in a given production environment.

A system is provided for encoding job-specific identification information to be extracted by the same spectrophotometric scanner as is typically used in existing calibration systems. Since scanning software can read job-specific identification information from a printed page containing target color patches, it is
15 not necessary for a human operator to have expertise in handling printed pages and scanner results. The use of predefined start codes as part of the data encoding scheme allows early detection of major print problems such as separation drop out. Also, it enables an ability of the software to check for simple errors in page positioning such as placing the page on the scanner in a wrong orientation. Positioning errors are accounted for in the software and the scanned page is
20 processed correctly without human intervention. This greatly enhances the robustness of the scanning part of the calibration process. Having job identification information stored within the page and machine readable output from the scanner results in the operator not having to track which scanner output is associated with a particular printer or target. Software can be used to track a
25 calibration state without human intervention, thus reducing the potential for errors, and providing increased robustness to the system.

DESCRIPTION OF THE DRAWINGS

The present invention exists in the construction, arrangement, in
30 combination of the various parts of the device, and steps of the method, whereby the objects contemplated are attained as hereinafter more fully set forth, specifically pointed out in the claims, and illustrated in the accompanying drawings in which:

FIGURE 1 illustrates an exemplary protocol for encoding binary values
35 into patch codes;

FIGURE 2 depicts an exemplary patch code format;

FIGURE 3 illustrates an exemplary format for using patch codes in an application; and,

FIGURE 4 shows pages rotated from a preferred position.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

5 There are many techniques for encoding information onto a printed page, glyphs, Cauzin strips and bar codes for example. However, these are typically read by scanners designed to handle a specific type of data. Glyphs require two-dimensional platen scanning. Cauzin strips require the Cauzin strip reader or two-dimensional platen scanning with appropriate software. Handheld laser scanners
10 are typically used to read bar codes. For color calibration applications, in order to maximize robustness, it is desirable to minimize the number of times a human operator has to manipulate printed pages. It is therefore preferable to have a scanner that scans for spectrophotometric values (calibration data) also scan for job identification information. A spectrophotometric scanner typically used for
15 calibration moves to a particular coordinate and then commences scanning for color values. One such scanner may be a Gretag spectrophotometer (from Gretag Imaging Inc.). Use of a scanner of this type results in implementation of an encoding scheme that will function in that mode, wherein job identification data is printed according to a protocol and in a format approximately identical to the
20 format of the calibration data. A patch code scheme satisfies the aforementioned issues.

 A patch code is a sequence of color patches, each of which is selected from a set of colors that are readily distinguished from each other on any printer, whether or not it is calibrated. Good candidates for patch codes are the primary
25 colorants cyan, magenta, yellow, the secondary mixtures red, green, blue, paper white, and mid-gray. Black is not used because of possible confusion with blue. Also, rendition of a good black often requires an optimum combination of cyan (C), magenta (M), yellow (Y), and black (K). This requires intimate knowledge of the printing process, which may not be known at the time of calibration. This set
30 of 8 patch codes allows each patch to encode 3 bits of data, or a single digit in an octal numbering system.

 For example, an octal digit represents one integer in the range 0-7 which can alternately be represented by a three digit binary integer in the range 000-111. A single row of twenty patch codes can encode up to sixty bits of data. Four such
35 rows can encode up to two hundred and forty bits of information.

 To use patch codes, a protocol is defined. Figure 1 illustrates an exemplary encoding scheme 10 of binary values into patch codes. Normally each

color patch is a different color, however, to distinguish each of the eight colors on a black-and-white document, each color is represented in Figure 1 and all remaining figures by a unique format of cross hatches, dots or shade of gray. A cyan color patch 12 is represented by diagonal cross hatching that slopes downward towards the right side. A magenta color patch 14 is represented by diagonal cross hatching that slopes upward towards the right side. A yellow color patch 16 is represented by vertical cross hatching. A white color patch 18 is represented by a pattern of dots. A red color patch 20 is represented by horizontal cross hatching. A green color patch 22 is represented by a checkerboard pattern. A blue color patch 24 is represented by diagonal cross hatching. Finally a midgray color patch 26 is represented by a solid shade of gray.

Figure 2 illustrates one possible format for a two row, twenty column patch code 30. The first three color patches of the first row, has the colors cyan 12, magenta 14 and yellow 16, in that order, forming a start code 32. This code is a confirmation to the system that the patches about to be encountered are patch codes. If the start codes are not encountered at the very beginning of the measurement file, the system will suspect incorrect orientation of the target. This can then potentially be corrected at the very onset of the measurement processing step. The next two color patches represent a number of rows 34, in octal, of patch code 30. In the exemplary patch code in Figure 2, a cyan-yellow pair of color patches is shown, indicating a total number of 2 rows. The following two color patches represent the number of columns 36, or width, of patch code 30 in terms of the number of color patches per row. The example shows a yellow-red pair of color patches, indicating an octal 24, or 20 color patches per row. The next two color patches represent a patch code version number 38, currently set to 1 (i.e. cyan, magenta). The patch code version number will be incremented when new fields are added or fields are changed to an initial patch code. Remaining color patches in patch code 30 represent job or other data depending on a specific format of the patch code version number 38. For exemplary version 1, the following information is encoded:

- a job ID 40, 33 bits in length, containing a unique ID used as a key to access a state of a given printer calibration;
- a date 42, 33 bits in length, containing a print file creation time in seconds from January 1, 1970 or other selected time;
- a page number 44, 6 bits in length, containing a calibration page number;
- a target type 46, 3 bits in length, identifying what type of color target is printed on a page containing patch code 30;
- a sub ID 48, 6 bits in length, used to track experimental variations from the

standard calibration path; and,

extra unused color patches 50 can be printed with any appropriate code, midgray corresponding to an octal 7 is shown in the example.

Other information which can be included in the patch code as it suits the user's application. For example, recording the type of marking technology, for example, xerographic versus inkjet versus dye sublimation, etc., may be of considerable value in optimizing the calibration process. Recording the type of medium, for example, coated paper stock, uncoated matte stock, etc., may also be of value in calibration.

The two-row patch code 30 illustrated in Figure 2 can encode 93 bits of job information, with an additional 27 bits used for a start code 32, number of rows 34, number of columns 36 and version number 38. Adding an additional row would add an additional 60 bits of job information. The format illustrated uses 20 color patches in a single row while a typical printed page, U.S. legal size for example, is 8.5 inches minus whatever margins or hardware limitations may exist for a printer. Hardware limitations may reduce the overall printable width to 7 inches which would allow for 28 color patches, each 1/4 inch wide, across a single page. However, since the locations of the start codes 32 must be well defined and unique to identify page rotations as explained below, a good choice is to select 20 color patches per row as typical. This is, of course, exemplary and can be adjusted for other applications.

As described above, start code 32 is in a fixed location relative to patch code 30, preferably as the first three color patches of patch code 30 as illustrated in Figure 2. Placing start code 32 in the aforementioned position, and placing patch code 30 near the upper-left margins (as it is to be scanned) of a printed page provides several advantages.

Use of the present invention permits scanner software to easily check for rotations of a page, or mispositioning of a page by checking several locations that correspond to common rotations or mispositioning of the page as illustrated in Figures 3 and 4. In Figure 3, a printing device 59 holds a page 60, containing targets 62 and 64. Page 60 represents a page in a preferred orientation with respect to a spectrophotometric scanner system 65 to which page 60 will be transported for scanning, wherein the rows of patch code 30 are aligned in a preferred horizontal direction. The scanner system 65 first scans for start code 32 in the upper left corner of page 60, and having found start code 32 can assume that page 60 is correctly oriented and commence scanning for targets 62 and 64 in their preferred positions. Following the scanning process, readable spectrophotometric scan results are obtained by the scanner system 65, including the job identification

data and calibration data. In an alternative embodiment, a system external to the scanner system 65 may be used to obtain the job identification data and calibration data.

Page 66 of Figure 4 represents page 60 in a first rotated position, wherein start code 32 is now in the top right corner of page 66, and the rows of patch code 30 are now vertically aligned. The spectrophotometric scanner system 65 of Figure 3 will first search for start code 32 in its preferred position, and having not found it there will search in a first alternate location for start code 32 as illustrated in page 66. Having found start code 32 in a first alternate position, the scanner can subsequently scan for targets 62 and 64 in their corresponding rotated positions. Pages 68 and 70 represent page 60 in second and third alternate rotations respectively. The spectrophotometric scanner system 65 would scan for start code 32 in second and third alternate positions only after failing to find start code 32 in previously scanned positions. In this manner, the scanner can detect for misrotated pages and, by scanning additional alternate positions, can detect mispositioned pages as well.

In an alternative embodiment the scanner would always scan the target in the same manner regardless of orientation of the printed page. A measurement processing system that is external to the scanner system would be used to search for the start code and appropriately rotate and reorder the spectrophotometric data to the intended sequence.

Implementing a patch code permits the scanner software to quickly check that all separations of the printer are functioning correctly. After scanning for start code 32 in preferred and alternate rotations and positions, if the spectrophotometric scanner has failed to find start code 32, the scanner can provide an error indication to a user. This error indication would of course indicate that job ID 40 could not be found, and corrective action must be taken by a scanner operator.

The automation provided by the present invention eliminates the need of an operator to manually keep track of all calibration pages, the source printer and targets for each page, and the results of spectrophotometric scanning of each target-containing page. In a production environment wherein perhaps 30 to 40 printers are being calibrated at any one time, there is a very real possibility that mishandling can occur, especially considering that many target types can be printed for each printer. Pages can be accidentally placed out of order, and target scanning results can consequently be associated with an incorrect printer or an incorrect target type. The present invention provides a means of breaking the cycle where an operator must keep track of everything. The operator can simply

feed target-containing pages to a scanner, and the scanner software can perform all of the tracking and identification details with a greatly reduced possibility for error.

5 The invention has been described with reference to the preferred embodiments. Obviously, modifications and alterations will occur to others upon a reading and understanding of this specification. It is intended to include all such modifications and alterations insofar as they come within the scope of the appended claims or the equivalents thereof.

Having thus described the invention, I hereby claim:

1. A color calibration job identification system comprising:
a printed page on which at least one color target is printed; and,
a patch code printed on the page to provide additional data useful to the
color calibration.
2. The color calibration job identification system according to claim 1,
wherein said patch code comprises:
a first portion including a start code, wherein said start code includes two
or more color patches wherein each of said patches have a predefined color; and,
a second portion comprising job identification data, wherein said job
identification data includes two or more color patches wherein each of said
patches is comprised of a color selected from a plurality of colors, each indicative
of a unique datum value.
3. The color calibration job identification system according to claim 2,
wherein said start code assists in determining correct functioning of a printer.
4. The color calibration job identification system according to claim 2,
wherein said start code assists in determining an orientation of said printed page in
a scanning device.
5. The color calibration job identification system according to claim 2,
wherein said patch code comprises a rectangular array of color patches.
6. The color calibration job identification system according to claim 5,
wherein said patch code includes:
one or more color patches defining a number of rows of said rectangular
array; and,
one or more color patches defining a number of columns of said
rectangular array.
7. The color calibration job identification system according to claim 2,
wherein said patch code includes one or more color patches defining a target type.

8. The color calibration job identification system according to claim 2, wherein said patch code includes one or more color patches specifying the type of marking technology.

10 9. The color calibration job identification system according to claim 2, wherein said patch code includes one or more color patches specifying the type of medium on which the patches are printed.

10. The color calibration job identification system according to claim 1, wherein said patch code includes a plurality of data sub-patch codes including, but not limited to:

5 date by time;
page number; and,
sub ID codes.

11. The color calibration job identification system according to claim 2, wherein said color patches comprise an octal numbering system, and each of said color patches is printed with a color selected from one of eight distinguishable colors such as, but not limited to cyan, magenta, yellow, white, red, green, blue and midgray.

12. The color calibration job identification system according to claim 9, wherein each of said colors exclusively represents an octal digit not less than 0 and not greater than 7.

5 13. The color calibration job identification system according to claim 2, further including a patch code encoding system comprising:
means for converting job identification data into a patch code; and
means for converting the patch code into a sequence of device signals to be sent to the printer.

10 14. The color calibration job identification system according to claim 2, further including a spectrophotometric scanner system which reads said start code, said job identification and said color targets and produces machine readable spectrophotometric scan results including said job identification data and
5 calibration data.

15. The color calibration job identification system according to claim 2, further including a spectrophotometric scanner system which reads said start code, said job identification and said color targets and produces human readable spectrophotometric scan results including said job identification data and calibration data.

16. A method for encoding job identification on a printed page on which at least one color target is printed and for scanning said printed page for said job identification data and said calibration data comprising:

converting job identification information to a patch code;

5 converting the patch code into a sequence of device signals to be sent to the printer;

printing a first portion of a patch code including a start code on said printed page, wherein said start code includes two or more color patches wherein each of said patches is comprised of a predefined color;

10 printing a second portion of a patch code including job identification data wherein said job identification data includes two or more color patches wherein each of said patches is of a color selected from a plurality of colors, each of said colors indicative of a unique datum value;

printing one or more color targets;

15 scanning said printed page with a spectrophotometric scanner system for said start code, said job identification and said color targets; and,

generating spectrophotometric scan results including said job identification data and calibration data.

17. The method as set forth in claim 16, further comprising:

determining correct functioning of a printer by confirming a presence of said start code.

18. The method as set forth in claim 16, further comprising:

determining an orientation of said printed page in said spectrophotometric scanner system by scanning alternate corners of said printed page until a start code is found, and assuming a default orientation if said start code cannot be found.

19. The method as set forth in claim 16, further comprising:

printing said patch code as a rectangular array of color patches including:

printing one or more color patches defining a number of rows of said rectangular array; and,

5 printing one or more color patches defining a number of columns
of said rectangular array.

20. The method as set forth in claim 16, further comprising:
 printing job and target identifying data in said job identification, including
at least one of:

 target type;
5 date by time;
 type of marking technology;
 type of medium;
 page number; and,
 sub ID codes.

21. The method as set forth in claim 16, further, wherein said converting of
patch code into a sequence of device signals comprise an octal numbering system,
and each of said color patches is printed with a color selected from one of eight
distinguishable colors such as, but not limited to cyan, magenta, yellow, white,
5 red, green, blue and midgray.

22. The method as set forth in claim 21, wherein each of said colors
exclusively represents an octal digit not less than 0 and not greater than 7.

PATCH CODES FOR COLOR CALIBRATION JOB IDENTIFICATION ENCODING

ABSTRACT OF THE DISCLOSURE

5 A color calibration job identification system and method are provided,
wherein the job identification data is encoded on a printed page, in a patch code,
along with color targets, according to a protocol and format approximately
identical to a format of the color targets. The patch code comprises a first portion,
including a start code, and a second portion, including job identification data. The
first portion of the patch code is comprised of two or more small color patches,
10 each having a predefined color. The second portion of the patch code is
comprised of two or more small color patches wherein each of the patches is
comprised of a color selected from a plurality of colors, wherein each of the colors
is indicative of a unique datum value, preferably an octal digit. The system
provides a means for determining correct functioning of a printer and a means for
15 determining an orientation of a printed page in a scanning device.

DECLARATION AND POWER OF ATTORNEY FOR PATENT APPLICATION

Attorney's Docket No. XER 2 0349
D/99605

As a below inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name,

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

PATCH CODES FOR COLOR CALIBRATION JOB IDENTIFICATION ENCODING

the specification of which

 x is attached hereto OR was filed on
Application Serial No.
and was amended on (if applicable)

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the patentability of this application in accordance with Title 37, code of Federal Regulations, Section 1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, Section 119 or 365(b) of any foreign application(s) for patent or inventor's certificate, or 365(a) of any PCT international application which designated at least one country other than the United States of America, listed below and have also identified below any foreign application(s) for patent or inventor's certificate or of any PCT international application having a filing date before that of the application on which priority is claimed:

Prior Foreign Application(s):

_____	_____	_____
(Number)	(Country)	(Filing Date)

I hereby claim the benefit under Title 35, United States Code, § 119(c) of any United States provisional application(s) listed below:

Prior Provisional U.S. Patent Application(s):

_____	_____
(Application Serial No.)	(Filing Date)

I hereby claim the benefit under Title 35, United States, Section 120 of any United States application(s) or any PCT international application designating the United States of America, listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application or PCT International application in the manner provided by the first paragraph of Title 35, United States Code, Section 112, I acknowledge the duty to disclose material information which is material to patentability as defined in Title 37, of Federal Regulations Code, Section 1.56(a) which became available between the filing date of the prior application and the national or PCT international filing date of this application:

Prior U.S. Patent Application(s):
